# FactGrid Cuneiform Discovery Project: Building Linked Open Data Repositories

FactGrid AWCA Google Drive & Google Colab

• FactGrid Cuneiform AWCA GitHub Org. Repos

Our Cuneiform project in FactGrid is building language support for all languages written in cuneiform, a writing system used for about 4000 years (from 3200 BCE to 50 CE). We are working with more than 350k documents to build dictionaries for these languages and social network graphs for the people, places, other entities named in these texts.

The main challenge we're working on is how to build reproducible workflows for linking four online databases of cuneiform sources (each with more than 100k documents) with two datasets of secondary sources. We're using Python notebooks (ipynb) to harmonize these open source databases, and we are linking the results using FactGrid Cuneiform, which is a triple store (or database for RDF triple statements). Our work helps us deepen our knowledge of Python for NLP and SparQL, the query language for Wikidata.

"Data is a precious thing and will last longer than the systems themselves."

Tim Berners-Lee, Inventor of the World Wide Web

This project is inspired by the durability of the data preserved in the oldest writing system known to mankind, called **cuneiform**. There are approximately a half-million artifacts with cuneiform writing spread all over the planet. Many of these objects are not even photographed, let alone translated. Scholars in this field have made a number of relational text databases, in order to identify these objects housed in museums and private collections, and while these databases have helped create a system of identification and textual analysis, they have yet to be linked together to each other and to the existing scholarship.

FactGrid is a Wikibase triplestore designed for historical research, which makes this the ideal hub for linking the existing scholarship, both primary and secondary sources, for every cuneiform artifact in publication. As a graph database (using RDF triples), this system allows for an expansive number of relationships to exist between any objects or entities, and for these relationships to be classified for greater discoverability. Additionally, the structure of a graph database provides simple solutions to duplication, disambiguation, and alternative editions of the same entity, which allows for a more comprehensive approach for linking the different datasets in various languages. Because the database is in Wiki(data) format, this provides an open forum for editing and collaborating internationally, which makes the data more robust, timely, and sustainable.

BERT & D2V

Entities I and J can be related based on shared references.

docs A, B, C, & D have similarities based on shared contexts.

#### **Concepts of Linked Data and bibliographic coupling**

Entities I and J are items with URIs, for example in Wikidata. Such items can be attested bibliographically and cited by documents C and D. The documents which cite these entities can be bibliographically coupled and their relational values can be measured by a count-frequency and cosine similarity scores.

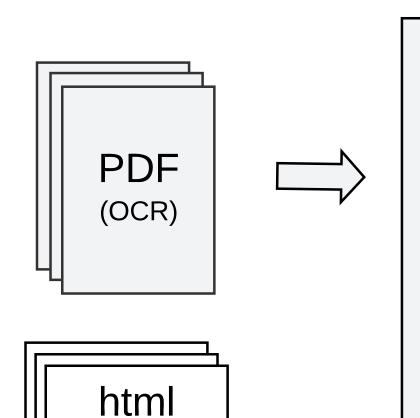

D

**NER** 

Topic Model (LDA)

Entities I and J are assigned the same topic number. Topic weight determines directedness of edges.

Sources are more representative of a topic or genre, based on TF-IDF + LDA

WIKIDATA

The goal for this project is to link every cuneiform artifact on record to the primary and secondary sources, which make explicit reference to the given object, and to extend this referencial system to include the entities named on each artifact (i.e. people, places, and things)
